Anti-tumoral action of cannabinoids on hepatocellular carcinoma: role of AMPK-dependent activation of autophagy

D Vara¹, M Salazar², N Olea-Herrero¹, M Guzmán², G Velasco²³ and I Díaz-Laviada*,¹³

Hepatocellular carcinoma (HCC) is one of the most common solid tumors and the third leading cause of cancer-related death worldwide.¹ Its prognosis remains reserved, with a 5-year survival rate of <5%.² It is the most common cause of death in patients with cirrhosis³ and, according to the World Health Organization, the incidence of HCC is expected to increase until 2030. The overall survival of patients with HCC has not significantly improved in the past two decades. Current treatments are only applicable at early stages of tumor development and include tumor resection, liver transplantation, chemoembolization and sorafenib administration.⁴ However, approximately half of the patients suffer tumor recurrence. The most important mechanism of liver cancer progression is cell proliferation. Although in recent years several clinical trials have tested the efficacy of agents that selectively target important signaling pathways involved in the control of this process, no relevant improvement in the prognostic/survival of patients with HCC has been achieved so far,⁵ and, therefore, it is necessary to identify novel therapeutic strategies for the management of HCC.

Hepatocellular carcinoma (HCC) is the third cause of cancer-related death worldwide. When these tumors are in advanced stages, few therapeutic options are available. Therefore, it is essential to search for new treatments to fight this disease. In this study, we investigated the effects of cannabinoids—a novel family of potential anticancer agents—on the growth of HCC. We found that Δ⁹-tetrahydrocannabinol (Δ⁹-THC, the main active component of Cannabis sativa) and JWH-015 (a cannabinoid receptor 2 (CB₂) cannabinoid receptor-selective agonist) reduced the viability of the human HCC cell lines HepG2 (human hepatocellular liver carcinoma cell line) and HuH-7 (hepatocellular carcinoma cells), an effect that relied on the stimulation of CB₂ receptor. We also found that Δ⁹-THC and JWH-015-induced autophagy relies on telomere repeat binding factor 3 (TRB3) upregulation, and subsequent inhibition of the serine–threonine kinase Akt/mammalian target of rapamycin C1 axis and adenosine monophosphate-activated kinase (AMPK) stimulation. Pharmacological and genetic inhibition of AMPK upstream kinases supported that calmodulin-activated kinase kinase (CaMKK) activation was responsible for cannabinoid-induced AMPK activation and autophagy. In vivo studies revealed that Δ⁹-THC and JWH-015 reduced the growth of HCC subcutaneous xenografts, an effect that was not evident when autophagy was genetically or pharmacologically inhibited in those tumors. Moreover, cannabinoids were also able to inhibit tumor growth and ascites in an orthotopic model of HCC xenograft. Our findings may contribute to the design of new therapeutic strategies for the management of HCC.

Cannabinoids are lipid mediators originally isolated from the hemp plant Cannabis sativa that produce their effects by activating primarily two G-protein-coupled receptors: cannabinoid receptor 1 (CB₁), which is highly abundant in the brain, and cannabinoid receptor 2 (CB₂), which is mainly expressed in non-neural tissues. Recently, numerous studies have evidenced the role of cannabinoids as potential anti-tumoral drugs owing to their ability to reduce tumor in different animal models, including glioma,⁶ breast cancer,⁷,⁸ and prostate cancer.⁹,¹⁰ Recent research has also reported that the synthetic cannabinoid WIN-55,212-2 inhibits HCC growth.¹¹,¹²

It has been described that Δ⁹-tetrahydrocannabinol (Δ⁹-THC), the main active constituent of marijuana, triggers human glioma cell death through stimulation of an ER stress pathway that activates autophagy and promotes apoptosis.¹³,¹⁴ Autophagy is a cellular self-digestive process whereby bulk cytoplasmic components and intracellular organelles are sequestered into double-membrane vesicles named autophagosomes and delivered for degradation to the

In the liver, autophagy may have an important role in the regulation of energy balance for basic cell functions. Inhibiting functional autophagy acts as a metabolic stress buffer, many lines of evidence support a role for autophagy in antagonizing cell survival and in promoting cell death and apoptosis. Autophagy has an important role in cancer, and inhibition of this cellular process has been proposed to contribute to HCC progression, and, therefore, it is a potentially very important target for liver cancer prevention and treatment.

This study was therefore undertaken to evaluate the potential anti-tumoral activity of cannabinoids in HCC and the mechanisms responsible for cannabinoid action in that devastating disease. We found that, both in cell cultures and in xenografted mice, Δ^9-THC and the synthetic CB2 receptor-selective agonist JWH-015 promote human HCC death via autophagy stimulation. We also provide a molecular mechanism underlying CB2 receptor-mediated anti-tumoral signaling. These observations may pave the way to the design of novel therapeutic strategies for the treatment of hepatocellular carcinoma.

**Results**

Δ^9-THC- and JWH-015-induced autophagy and apoptosis relies on CB2 receptor activation. To investigate the activity of cannabinoids on HCC cells, we first analyzed the effect of Δ^9-THC (a CB1/CB2 receptor-mixed agonist that constitutes the main psychoactive ingredient of Cannabis sativa) and JWH-015 (a CB2 receptor-selective agonist) on HepG2 (human hepatocellular liver carcinoma cell line) and HuH-7 (hepatocellular carcinoma cells), two HCC lines that express CB1 and CB2 cannabinoid receptors (Supplementary Figure 1A). Treatment with Δ^9-THC reduced the viability of HepG2 cells, an event that was prevented by co-incubation with SR144528 (SR2, a CB2 receptor-selective antagonist), but not with SR141716A (SR1, a CB1 receptor-selective antagonist) (Supplementary Figure 1B). Likewise, JWH-015 decreased the viability of HCC cells, and co-incubation with SR2 abrogated this effect (Supplementary Figure 1B). These observations support that stimulation of CB2 receptors is responsible for the decrease of cell viability triggered by cannabinoids on HCC cells.

Δ^9-THC and JWH-015 inhibit the growth of the human HCC lines HepG2 and HuH-7 via autophagy stimulation. It has been recently shown that cannabinoids induce human glioma cell death via autophagy stimulation in vitro and in vivo. We therefore examined whether Δ^9-THC and JWH-015 activate a similar mechanism in HCC cells. Upon autophagy stimulation, the autophagy protein LC3 (microtubule-associated protein 1 light chain 3α) becomes conjugated to phosphatidylyethanolamine (PE), which targets this protein to the membrane of the autophagosomal membranes. The lipidated autophagosome-associated form of LC3 (LC3-II) can be monitored by immunofluorescence (autophagic cells exhibit a characteristic pattern of LC3 puncta) or western blot (LC3-II has higher electrophoretic mobility than non-lipidated LC3). Immunofluorescence analysis revealed that LC3 exhibited a punctuated distribution, consistent with its translocation to the autophagosome, in cells that had been treated with Δ^9-THC or JWH-015 (Figure 1a). Likewise, incubation of HepG2 and HuH-7 cells with Δ^9-THC or JWH-015 increased the levels of the lipidated form of LC3 (Figure 1b).

Furthermore, pharmacological inhibition with E64d and pepstatin A (PA) of lysosomal proteases (the enzymes responsible for the degradation of the autophagosome content after fusion with the lysosome) enhanced the accumulation of LC3-II (as well as of the autophagosome cargo p62) in cells that had been treated with THC or JWH-015, thus supporting the fact that cannabinoid treatment leads to dynamic autophagy in HCC cells (Figure 1b).

Next, we investigated whether autophagy was directly involved in the mechanism of cannabinoid-induced cell death. As shown in Figure 1c, cell death was inhibited when autophagy was pharmacologically blocked at a very early stage (by incubation with 3-methyadenine (3-MA), an inhibitor of Vps34, a class III phosphatidyl inositol-3-kinase that has a crucial role in autophagy initiation or at a final stage (by incubation with E64d and PA). Likewise, knock down of Atg5 (an essential autophagy gene that is part of one of the two protein conjugation systems required for autophagosome elongation) or impaired TRC- or JWH-015-induced cell death (Figure 1d). Taken together, these observations strongly support that autophagy is required for cannabinoid-induced HCC cell death.

Many lines of evidence indicate that there is a cross-talk between autophagy and apoptosis. To investigate whether cannabinoid-induced autophagy was involved in apoptosis induction, HepG2 and HuH-7 cells were incubated with either Δ^9-THC or JWH-015 in the presence of the 3-MA, and levels of procaspase-3 were detected by immunoblot. As shown in Figure 1e, pre-incubation with 3-MA prevented the cleavage of procaspase-3, suggesting that autophagy induction by cannabinoids was previous to and necessary for apoptosis.

AMPK activation and TRB3 upregulation are involved in Δ^9-THC- and JWH-015-induced autophagy and apoptosis of HCC cells. The mechanisms of autophagy stimulation by cannabinoids in glioma and other types of cancer cells rely on the stimulation of an ER stress-related pathway, which leads to the upregulation of the pseudokinase telomere repeat binding factor 3 (TRB3). This latter protein interacts with serine–threonine kinase Akt (Akt) and promotes the inhibition of the mammalian target of rapamycin C1 (mTORC1) complex, which leads to autophagy stimulation. As shown in Figure 2, THC and JWH-015 increased the phosphorylation of the α-subunit of the eukaryotic translation initiation factor 2 (eIF2α), a hallmark of the ER stress response; Figure 2a), increased TRB3 levels (Figure 2b) and decreased the phosphorylation of Akt, p70S6 kinase (a well-established substrate of mTORC1) and the ribosomal protein S6 (a target of p70S6 kinase) in HepG2 and HuH-7 cells (Figure 2c). Furthermore, selective knockdown of TRB3 abrogated cannabinoid-induced inhibition of the Akt/mTORC1 pathway, autophagy and cell death (Supplementary Figure 2), thus supporting the fact that...
the mechanism by which cannabinoids promotes glioma cell death also operates in HCC cells.

Of note, we observed that treatment of HepG2 and HuH-7 cells with THC or JWH-015 increased the phosphorylation of adenosine monophosphate-activated protein kinase (AMPK), an important intracellular nutrient status sensor that has been proposed to have a critical role in the regulation of autophagy as induced by hypoxia or nutrient deprivation.
In addition, pharmacological blockade of CB2 receptors with SR2 abrogated the effect of D9-THC and JWH-015 on Akt, S6 and AMPK phosphorylation, as well as autophagy (Figure 2d and Supplementary Figure 1C). We therefore asked whether AMPK may also have a role in the regulation of the antiproliferative effect evoked by cannabinoids in HCC cells. In line with this notion, when AMPK was pharmacologically blocked with dorsomorphin (Figure 3a) or genetically inhibited with small interfering RNA (siRNA) (Figure 3b), HepG2 and HuH-7 cells were more resistant to cannabinoid-induced cell death. Likewise, AMPK knockdown prevented LC3 lipidation (Figure 3c and Supplementary Figure 2C). These observations support the fact that activation of AMPK is necessary for the anti-tumoral action of cannabinoids on HCC.

Figure 2  Δ9-Tetrahydrocannabinol (Δ9-THC) and JWH-015 upregulate telomere repeat binding factor 3 (TRB3), inhibit the serine–threonine kinase Akt/mammalian target of rapamycin C1 (Akt/mTORC1) pathway and activate adenosine monophosphate-activated kinase (AMPK) through cannabinoid receptor 2 (CB2) receptors. (a) Effect of Δ9-THC or JWH-015 (8 h) on the phosphorylation of eIF2α in HepG2 and HuH7 cells. Tubulin levels are shown as a loading control. The image is representative of three different experiments. (b) Effect of Δ9-THC or JWH-015 (24 h) on telomere repeat binding factor 3 (TRB3) mRNA levels (as determined by quantitative polymerase chain reaction (qPCR)) of HepG2 and HuH7 cells (n = 4; **P < 0.01). (c) Effect of Δ9-THC or JWH-015 (24 h) in the phosphorylation of AMPK, Akt, p70S6K and S6 of HepG2 and HuH7 cells. Tubulin levels are shown as a loading control. The image is representative of three different experiments. (d) Effect of Δ9-THC (8 μM), JWH-015 (8 μM), 1 μM SR141716A (SR1) or 2 μM SR 144528 (SR2) (24 h) on AMPK, Akt and S6 phosphorylation, as well as microtubule-associated protein 1 light chain 3 alpha (LC3) lipidation of HepG2 cells. Tubulin levels are shown as loading control. The image is representative of five different experiments. Optical density (O.D.) values (mean ± standard deviation (S.D.) of the five experiments; *P < 0.05 and **P < 0.01 versus control) are shown under the each image.
stimulation of autophagy-mediated cell death by cannabinoids in HCC cells.

AMPK and TRB3 regulate cannabinoid-induced autophagy of HCC cells through different mechanisms. AMPK has been shown to inhibit mTORC1.28 Unlike Akt, AMPK activates tuberous sclerosis complex 2 (TSC2), a GTPase-activating protein responsible for the blockade of mTORC1. Therefore, we next studied whether this was the mechanism by which AMPK stimulated autophagy in our system. As shown in Figure 3c and Supplementary Figure 2C, AMPK silencing abrogated the effect of Δ⁹-THC and JWH-015 in the...
phosphorylation of AMPK and its downstream target acetyl-CoA carboxylase (ACC), as well as on autophagy, but did not modify the effect of cannabinoid treatment on the phosphorylation of Akt, TSC2 (data not shown) or the mTORC1-related substrates 4EBP1 and S6. By contrast, TRB3 knockdown did not affect AMPK or ACC phosphorylation, but did inhibit the cannabinoid-induced decrease in Akt, TSC2, 4EBP1 and S6 phosphorylation and LC3 lipiddation. Likewise, pharmacological blockade of ceramide biosynthesis by using ISP-1 (a pharmacological inhibitor of serine palmitoyltransferase, one of the upstream events that trigger TRB3 upregulation in response to cannabinoid treatment) abrogated the effect of Δ⁹-THC on Akt, TSC2, 4EBP1 and S6 phosphorylation, as well as LC3 lipiddation, but did not affect AMPK phosphorylation. These observations support that the cannabinoid-evoked stimulation of autophagy on HCC cells relies on two different mechanisms: (i) inhibition of the Akt/mTORC1 axis via TRB3 upregulation and (ii) stimulation of AMPK. (A scheme is shown in Figure 5.)

**Activation of AMPK by cannabinoids relies on CAMKK.** We next investigated the mechanism by which cannabinoids activate AMPK. Among the different kinases proposed to act as AMPKKs, the human tumor suppressor liver kinase B1 (LKB1) and the calmodulin-activated kinase kinase (CaMKK) are now widely accepted as the most relevant ones. Inhibition of LKB1 expression with siRNA did not have any significant effect on the viability of cannabinoid-treated HepG2 (Figure 4a) or HuH7 (Supplementary Figure 3) cells. Likewise, the effect of cannabinoid treatment on AMPK activation, Akt/mTORC1 pathway inhibition and autophagy (LC3 lipiddation) was not affected by LKB1 silencing (Figure 4a), supporting the fact that LKB1 is not involved in cannabinoid-induced AMPK activation and autophagy in HCC cells. By contrast, selective knockdown of CaMKKβ or incubation with the CaMKK pharmacological inhibitor STO609 prevented the cannabinoid-evoked decrease in HCC cell viability (Figures 4b and c and Supplementary Figure 3), increase in AMPK and ACC phosphorylation (Figures 4b and c) and autophagy (Figures 4b and c), indicating that AMPK activation by cannabinoids in HCC cells relies on CaMKKβ. Of note, genetic or pharmacological blockade of CaMKKβ did not modify the inhibition of the Akt/mTORC1 pathway evoked by these agents, which again supports the fact that mTORC1 inhibition by cannabinoids in HCC occurs independently of AMPK activation (Figures 4b and c).

**Autophagy is required for Δ⁹-THC and JWH-015 anti-tumoral action in human HCC xenografts.** To investigate the ability of Δ⁹-THC and JWH-015 to inhibit HCC growth in vivo, we first generated tumor xenografts by subcutaneous inoculation of HepG2 or HuH-7 cells in nude mice. Mice were daily treated with vehicle (control), 15 mg/kg Δ⁹-THC or 1.5 mg/kg JWH-015 for 15 days. As shown in Figure 6a, cannabinoid administration almost totally blocked the growth of HepG2 cell-derived tumors. Moreover, treatment with Δ⁹-THC or JWH-015 enhanced AMPK phosphorylation and reduced Akt phosphorylation, which was accompanied by a decrease of S6 phosphorylation and an increase of LC3-II lipiddation (Figure 6b). Likewise, procaspase-3 levels were also decreased in cannabinoid-treated tumors (Figure 5b). Similar results were obtained with HuH-7 cell-derived tumors, in which Δ⁹-THC or JWH-015 administration also decreased tumor growth (Figure 6c), increased the AMPK phosphorylation, decreased Akt and S6 phosphorylation and enhanced LC3 lipiddation and caspase-3 activation (Figure 6d).

To further examine the role of autophagy on the anti-tumoral action of cannabinoids, another set of experiments was conducted to analyze the effect of cannabinoids on the growth of HepG2 tumor xenografts in which Atg5 expression had been knocked down in vivo. As shown in Figure 7a, Δ⁹-THC and JWH-015 failed to inhibit the growth of Atg5-silenced tumors, but not of those tumors that had been transfected with control siRNA. Furthermore, pharmacological inhibition of autophagy by using 3-MA prevented the decrease in tumor growth evoked by Δ⁹-THC and JWH-015 (Figure 7b). Taken together, these findings strongly support the fact that autophagy is necessary for the anti-tumoral action of cannabinoids in hepatocellular carcinoma.

Finally, we tested the anti-tumoral efficacy of cannabinoids in an orthotopic HCC model. HepG2 cells were inoculated in the liver of nude mice, and after 1 week, mice were treated intraperitoneally with vehicle (control), 15 mg/kg Δ⁹-THC or 1.5 mg/kg JWH-015 for 10 days. As shown in Figure 8a,
Cannabinoid treatment almost completely prevented hepato-megaly and ascites. Moreover, levels of the HCC tumor marker α-fetoprotein (AFP) were dramatically reduced in the livers of animals treated with Δ⁹-THC or JWH-015 (Figure 8b). Analysis of tumor samples revealed that cannabinoid treatment enhanced AMPK phosphorylation and inhibited Akt and S6 phosphorylation. Furthermore, THC and JWH-015 enhanced autophagy and apoptosis in these tumors (Figure 8a).

Taken together, these observations robustly support the fact that cannabinoid anti-tumoral action in HCC relies on AMPK stimulation, Akt inhibition and activation of autophagy in HCC cells both in vitro and in vivo.

Discussion

In this study, we show that the natural cannabinoid Δ⁹-THC and the CB₂ receptor-selective agonist JWH-015 inhibit HCC...
was partially inhibited by the CB2 receptor-selective antagonist, CAY-10624-induced apoptosis in HepG2 cells in a process that is involved in the pro-autophagic and antiproliferative effect of cannabinoids on these cells. This is in line with the recent observation that the synthetic cannabinoid WIN-55,212-2-induced apoptosis in HepG2 cells is a combined mechanism for cell death.32 However, very little is known about the role that the interchange between these two cellular processes have in the control of tumor growth in response to anticancer agents. Our observations are in line with previous results obtained in human glioma cells13 and support the fact that stimulation of autophagy in response to cannabinoid treatment leads to apoptosis. Nevertheless, further research is still necessary to clarify the precise mechanisms linking both cellular processes upon cannabinoid treatment.

Figure 5 Schematic of the proposed mechanism of cannabinoid-induced hepatocellular carcinoma (HCC) cell death. Cannabinoid treatment stimulates autophagy via two different mechanism: (i) upregulation of telomere repeat binding factor 3 (TRB3) and subsequent inhibition of the serine–threonine kinase Akt/mammalian target of rapamycin C (mTORC1) axis, and (ii) activation of adenosine monophosphate-activated kinase (AMPK) via CaMKKβ. Stimulation of autophagy by cannabinoids leads to HCC apoptosis and cell death.

Stimulation of autophagy in many cellular settings relies on the inhibition of the mTORC1 complex, which have a central role in the control of protein synthesis, cell growth and cell proliferation through the regulation of several downstream targets. As a result of its central position in the control of cellular homeostasis, mTORC1 integrates signals from different inputs. One of the most important upstream regulators of mTORC1 is the pro-survival kinase Akt, which phosphorylates and inactivates TSC2 (an inhibitor of the mTORC1 activator Rheb) and PRAS-40. Thus, Akt activation stimulates mTORC1 and inhibits autophagy. In this work, we found that cannabinoid treatment of HCC cells leads to Akt and mTORC1 inhibition, which is in agreement with our recent studies in glioma cells.13 Thus, it had been previously shown that inhibition of Akt/mTORC1 pathway by cannabinoids relies on the stimulation of an ER stress-related pathway, which leads to the upregulation of the pseudokinase TRB3, the inhibition of the Akt/mTORC1 axis and the induction of autophagy.13,23 In this study, Δ9-THC and JWH-015 promoted ER stress and increased TRB3 expression. In addition, Akt/mTORC1 inhibition and autophagy were abolished when ceramide biosynthesis was inhibited or when TRB3 expression was silenced, thus suggesting that this could be a general mechanism of cannabinoid anti-tumoral action. Of importance, we also found that Δ9-THC and JWH-015 activate AMPK in HCC cells and that pharmacological or genetic inhibition of this kinase has a similar inhibitory effect on cannabinoid-induced cell death and autophagy. AMPK has been shown to negatively regulate mTORC1 via TSC2 activation, which also leads to autophagy stimulation.33 and therefore we asked whether cannabinoids also inhibit mTORC1 through this mechanism in HCC cells. In disagreement with this possibility, our data show that – unlike TRB3 silencing – AMPK knockdown does not prevent cannabinoid-induced mTORC1 inhibition. In addition, knock down of TRB3 does not affect the stimulation of AMPK by cannabinoids. These observations suggest that TRB3 and AMPK (i) are activated by different mechanisms in response to cannabinoid treatment, and (ii) regulate autophagy acting at different stages.

Two converging pathways have been described for AMPK regulation: one directed by LKB1, dependent on a change in cellular AMP, and another one directed by CaMKKs, dependent on changes in intracellular Ca2+. The dramatic reduction in phosho-AMPK and phosho-ACC obtained upon silencing of CaMKKβ indicates that this latter kinase rather than LKB1 is the dominant AMPK kinase in HCC cells in response to cannabinoids. Thus, cannabinoids induce autophagy in HCC cells, possibly by a two-pronged mechanism, one prong (similar to that operating in glioma cells) involving ER stress, TRB3 and Akt/mTORC1 inhibition, and another one reliant on AMPK stimulation via CaMKKβ. A model of this mechanism of cannabinoid action in HCC cells is depicted in Figure 5.

In addition, it has been recently shown that AMPK binds to and directly phosphorylates the Ser/Thr kinase ULK1, the mammalian ortholog of the yeast protein kinase Atg1, and that this phosphorylation is required for ULK1-mediated autophagy.35,36 Thus, under certain cellular settings, mTORC1 inhibition and AMPK activation may cooperate to trigger

Cell Death and Differentiation
autophagy. Although future research is needed to completely clarify this point, our data suggest that this could be the mechanism by which cannabinoids trigger autophagy in HCC cells. 

To note, it has been recently described that mTOR signaling has a critical role in the pathogenesis of HCC and that mTOR inhibitors have antineoplastic activity in experimental models of HCC. Moreover, decreased autophagy in HCC correlates with a more aggressive cancer cell phenotype and poor prognosis. Here we found that cannabinoid treatment reduces the growth of two different models of HCC subcutaneous xenografts in concert with decreased mTORC1 activation, enhanced AMPK phosphorylation and increased autophagy and apoptosis in those tumors. Moreover, knock down of the autophagic gene Atg5 as well as pharmacological inhibition of autophagy dramatically abolished the antitumor activity of cannabinoids against subcutaneous HCC xenografts. Furthermore, Δ⁹-THC and JWH-015 efficiently reduced ascites development and AFP expression in an orthotopic model of HCC, which also paralleled mTORC1 inhibition, AMPK activation and autophagy stimulation in those tumors. Our data represent the first evidence for the antiproliferative action of cannabinoids in HCC cells in vivo and support that the ability of cannabinoids to inhibit mTORC1, stimulate AMPK and enhance autophagy could be therapeutically exploited for the management of HCC.

Materials and Methods

Reagents. Δ⁹-THC was obtained from GW Pharm GmbH (Frankfurt, Germany) and JWH-015 was purchased to Sigma (St. Louis, MO, USA). The CB₁ antagonist SR-141716 and the CB₂ antagonist SR-144528 were kindly provided from Sanofi-Synthelabo (Paris, France). The anti-LC3 polyclonal antibody was obtained from MBL International (Woburn, MA, USA) and the anti-pS6, pAKT-ser473, pACC, ACC, pelF2α, pAMPK and AMPK polyclonal antibodies were obtained from Cell Signaling Technology (Danvers, MA, USA). The anti-caspase-3 antibody and 3-MA were purchased to Sigma. The inhibitors E64d and PA were purchased to Roche Diagnostics (Mannheim, Germany). The CaMKKβ inhibitor STO609 was...
purchased from Sigma. Atelocollagen (AteloGene) was purchased to Cosmo Bio Co. (Tokyo, Japan). All the other chemicals were obtained from Sigma.

Cell cultures. Human HCC HepG2 cells (ATCC, HB-8065) (Rockville, MD, USA) were cultured according to suppliers. The human hepatoma cell line HuH-7 was kindly supply by Dr. Lisardo Bosca (Instituto de Investigaciones Biomédicas Alberto Sols, Madrid, Spain). Cells were routinely growth in DMEM/10% FBS supplemented with 1% non-essential amino acids and 100 µg/ml penicillin G sodium, 100 µg/ml streptomycin sulfate, 0.25 µg/ml amphotericin B (Invitrogen, Paisley, UK). One day before the experiments, the medium was changed to 0.5% FBS medium. Experiments were carried out when cell monolayers were 80% confluent.

RT-PCR analysis. Total RNA was isolated from cells by Trizol Reagent from Gibco (Invitrogen, Carlsbad, CA, USA) according to manufacturer’s protocol. One microgram total RNA was retrotranscribed to cDNA with the M-MLV Reverse transcriptase kit (Life Technologies, Carlsbad, CA, USA). Two microliters of RT reaction were then PCR amplified with specific primers for CB1: sense primer, Figure 7

Autophagy is required for the anti-tumoral action of Δ^2-tetrahydrocannabinol (Δ^2-THC) and JWH-015 on hepatocellular carcinoma (HCC) tumor xenografts. (a) Nocytic nude mice were injected subcutaneously (s.c.) in the right flank with HepG2 cells. When tumors reached a 150 mm^3 size, mice daily treated during 15 days with vehicle (control), 15 mg/kg Δ^2-THC or 1.5 mg/kg JWH-015. Tumors were injected with atelocollagen complexed with control RNA or atelocollagen complexed with small interfering (si)Atg5 in days 1 and 7 of the treatment. Tumor volumes were measured daily. Tumor growth curves and final tumor volumes after administration of the treatments are shown. Results represent the mean ± standard error of mean (S.E.M.) of eight mice in each group. **p < 0.01 versus control and ***p < 0.01 versus siControl compared by Student’s t-test. A representative image of the dissected tumors after the treatments is shown.

(b) Nocytic nude mice injected s.c. in the right flank with HepG2 cells were daily treated during 15 days with vehicle (control) (filled circles), 15 mg/kg Δ^2-THC (filled squares), 1.5 mg/kg JWH-015 (filled triangles), vehicle plus 1 mg/kg 3-MA (open circles), 15 mg/kg Δ^2-THC plus 1 mg/kg 3-MA (open squares) or 1.5 mg/kg JWH-015 plus 1 mg/kg 3-MA (open triangles). Tumor growth curves and final tumor volumes after administration of the treatments are shown. Results represent the mean ± S.E.M. of eight mice in each group. **p < 0.01 versus control and ***p < 0.01 versus cannabinoid-treated tumors compared by Student’s t-test. A representative image of the dissected tumors after the treatments is shown.

5′-TATATCTCTGGAGGCTCACAGCC-3′; antisense primer, 5′-GAGCATA CTGCA GAATGCAAACACC-3′ (for amplification of a 270-bp product for human CB1); and CB2: sense primer, 5′-TTTCCCACTGATCCCCAATG-3′; antisense primer, 5′-GAGCATACTGCAGAATGCAAACACC-3′ (for amplification of a 333-bp product for human CB2). PCR products were analyzed by electrophoresis on ethidium bromide-stained 2% agarose gels and DNA was detected by exposure under UV light.

Western blot. After different treatments according to the experiments cells were lysed in ice-cold lysis buffer (50 mM Tris (pH 7.4), 0.8 M NaCl, 5 mM MgCl2, 0.1% Triton X-100, 1 mM PMSF, 10 µg/ml soybean trypsin inhibitor, 1 µg/ml aprotinin and 5 µg/ml leupeptin), and cleared by microcentrifugation. Equivalent protein amounts of each sample were separated on SDS-PAGE gels and blotted to PVDF transfer membrane. After blocking with 5% skim dried milk, immunoblot analysis was performed followed by enhanced chemo luminescence detection.

Cell viability assay. Cells in logarithmic phase were cultured at a density of 5000 cells per cm2 in a 12-well plate. The cells were exposed to various concentrations of Δ9-THC and JWH-015 for indicated times. The 3-[4,5-dimethylthiazolyl-2]-2,5-diphenyl-tetrazolium bromide (MTT) cell viability assay was used to evaluate the effects of cannabinoids on cell growth and to determine the IC50.

Confocal microscopy. After 48 h in culture, the cells were fixed in 4% paraformaldehyde in PBS and incubated with 0.1% Triton X-100 for permeabilization. Immunolabeling with the anti-LC3 polyclonal antibody was performed by incubation...
at room temperature for 1 h. Secondary labeling was performed with Alexa Flour 594, conjugated to anti-rabbit IgG and Alexa Flour 488 (Invitrogen). Imaging was with a Leica TCS SP5 laser-scanning confocal microscope with LAS-AF imaging software, using a 63 × oil objective.

**siRNA transfections.** Cells were seeded at 2 × 10^4 cells/35 mm well the day before transfection. Cells were then transfected in 1 ml OPTIMEN containing 4 μg Lipofectamine 2000 (Invitrogen), with 100 nM siRNA duplexes or control scrambled RNA according to the manufacturer’s protocols. At 24 h after transfection, the medium was removed and replaced for DMEM containing 10% fetal bovine serum. Cells were then treated with cannabinoids for 48 h and used for MTT cell viability assays.

For each transfection, the following sequences were used: Atg 5 sense sequence, 5'-GUGGAAGAUGGUGUUAGAUAdTdT-3'; Atg 5 antisense primer, 5'-CCCAUGUCUUGAUUGUAUGAUG U-3'; Atg 5 antisense sequence, 5'-GACAUUGGAUUGUAUGAUAdTdT-3'; Atg 5 sense primer, 5'-AACAUUGGAUUGUAUGAUAdTdT-3'; Atg 5 sense sequence, 5'-GUGCCAGGCGCCGGCCGCUAdTdT-3'; LKB1 sense primer, 5'-GUCAUCUCUGACUCUGUAAUdTdT-3'; CaMKKβ sense primer, 5'-GCUCUCAUGGUGUUGUGCUAdTdT-3' (Sigma).

**Real-time quantitative PCR.** cDNA was obtained from cells using Transcripter (Roche Applied Science, Mannheim, Germany). Real-time quantitative (qPCR) assays were performed using the FastStart Universal Probe Master mix with Rox (Roche Applied Science), and probes were obtained from the Universal ProbeLibrary Set (Roche Applied Science). Atg 5 sense primer, 5'-GACGGCTGTTAAGTG4CAAGATG-3'; Atg 5 antisense primer, 5'-TAGGAGATCTCCAAGGGTATGCA-3'; TRB3 sense primer, 5'-GCCACGCTTGGCTCTTCCTG-3'; TRB3 antisense primer, 5'-GCTGCTTGGCCGAGATGGAT-3'; LKB1 sense primer, 5'-GGTGCAGGGAAGAATGGGCAAGC-3'; LKB1 antisense primer, 5'-ATGGGCTCTTGCTTTCG-3'; LKB1 sense primer, 5'-GGGTGTCTGTTCTGGATCAG-3'; LKB1 antisense primer, 5'-ACAAGCTGAGATGGTTCCTTTGG-3'. Amplifications were run in a 7900 HT-Fast Real-Time PCR System (Applied Biosystems, Foster City, CA, USA). Each value was adjusted by using 18S RNA levels as a reference.

**Animal care and handling.** Alimentary nude (nu/nu) 5-week-old male mice were obtained from Harlan Iberica Laboratory (Barcelona, Spain) and maintained under specific pathogen-free conditions with the approval of the Institutional Animal Care and Use Committee of Alcalá University. All animal studies were conducted in accordance with the Spanish institutional regulation for the housing, care and use of experimental animals and met the European Community directives regulating animal research. Recommendations made by the United Kingdom coordinating Committee on Cancer Research (UKCCCR) have been kept carefully.

**In vivo studies.** To study the in vivo antitumor activity of cannabinoids, hepatocarcinoma tumors were induced in athymic mice by subcutaneous injection or by liver implantation. Mice were injected subcutaneously in the right flank with 10 × 10^6 HepG2 or HuH-7 cells in 0.1 ml of PBS + 0.5% BSA. At 2 weeks after transplantation, tumors had grown to an average volume of 150 mm³. Mice were then divided into different experimental groups of eight animals each, which received the following treatments as subcutaneous injections according to the experiment: salmon (control); 15 mg/kg b.w. Δ^2-THC; 1.5 mg/kg b.w. JWH-015; and 1 mg/kg b.w. 3-MA. The injection was repeated every day and treatment was continued for 15 days. Tumor volumes were monitored every day using caliper measurements and were calculated by the formula: (4/3) × (w^2) × (l/2). The body weight of the animals was recorded daily. For in vivo Atg5 knockdown, xenograft tumors were induced as indicated and 1 nmol specific Atg5 atelocollagen-complexed siRNA or control siRNA was injected peritumorally on days 1 and 7 of the treatment.

**Statistical analysis.** Cell viability data were expressed as the mean ± S.D. and evaluated by Student’s t-test. Differences were considered significant when the p-value was less than 0.05.
